Introduction to Cryptography  
- Modern Block Ciphers

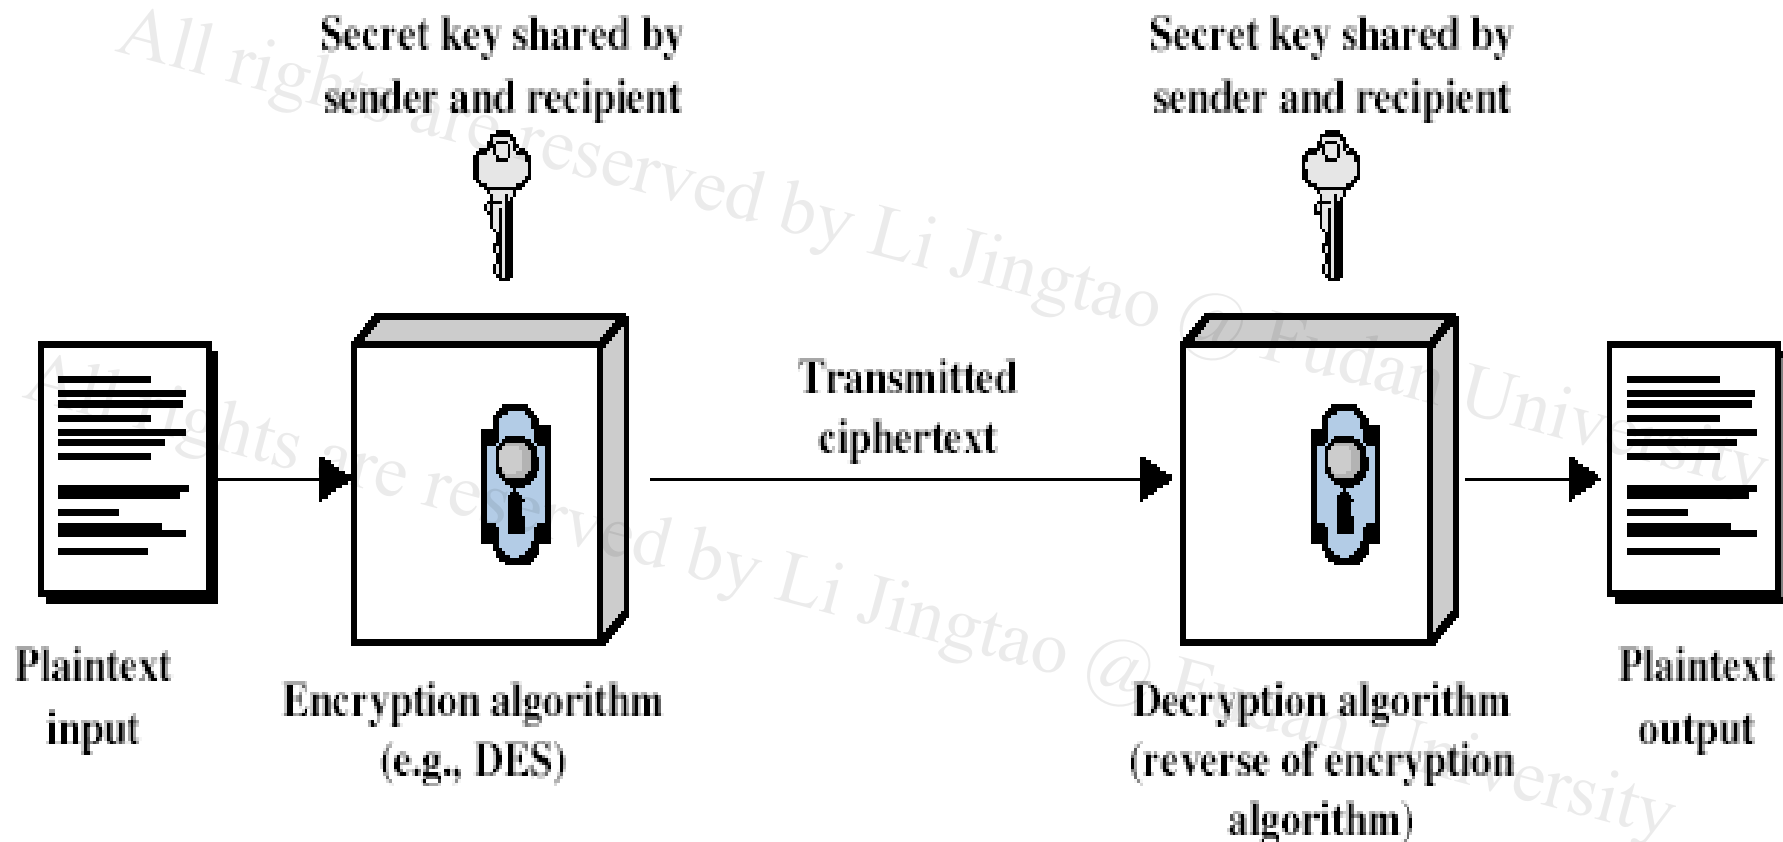

# Outline-Modern Block Ciphers

- now look at modern block ciphers
- one of the most widely used types of cryptographic algorithms
- provide **confidential/authentication** services
- focus on DES (Data Encryption Standard)
- to illustrate block cipher design principles

# Review: Symmetric Cipher Model

# Review

- **Monoalphabetic Cipher**

- **Playfair**

- **Vigenère Cipher**

# Review: Product Ciphers

- ciphers using substitutions or transpositions are not secure because of language characteristics
- hence consider using several ciphers in succession to make harder, but:
  - two substitutions make a more complex substitution
  - two transpositions make more complex transposition
  - but a substitution followed by a transposition makes a new much harder cipher
- this is bridge from classical to modern ciphers

# Block vs Stream Ciphers

- block ciphers process messages in blocks, each of which is then en/decrypted
- like a substitution on very big characters
  - 64-bits or more
- stream ciphers process messages a bit or byte at a time when en/decrypting
- many current ciphers are block ciphers
- broader range of applications

# Block Cipher Principles

- most symmetric block ciphers are based on a **Feistel Cipher Structure**
- needed since must be able to **decrypt** ciphertext to recover messages efficiently
- block ciphers look like an extremely large substitution
- would need table of  $2^{64}$  entries for a 64-bit block
- instead create from smaller building blocks
- using idea of a **product** cipher

# Ideal Block Cipher

# Ideal Block Cipher

Plaintext	Ciphertext
0000	1110

# Ideal Block Cipher->Feistel

- Feistel proposed
  - We can approximate the ideal block cipher by product cipher;
  - Develop a block cipher with a key length of  $k$  bits and a block length of  $n$  bits, allowing a total of  $2^k$  possible transformation
  - Rather than  $2^n!$

# Shannon and Substitution-Permutation Ciphers

- Claude Shannon introduced idea of substitution-permutation (S-P) networks in 1949 paper
- form basis of modern block ciphers
- S-P nets are based on the two primitive cryptographic operations seen before:
  - *substitution* (S-box)
  - *permutation* (P-box)
- provide **confusion** & **diffusion** of message & key

# Confusion and Diffusion

- cipher needs to completely obscure statistical properties of original message
- a one-time pad does this
- more practically Shannon suggested combining S & P elements to obtain:
- **diffusion** – dissipates statistical structure of plaintext over bulk of ciphertext
- **confusion** – makes relationship between ciphertext and key as complex as possible

# Shannon理论

- Shannon提出利用扰乱（**Confusion**）和扩散（**Diffusion**）交替的方法来构造乘积密码密码（**SPN, Substitution Permutation Network**：替代-置换网络）
- 目的为了使基于统计的分析方法不易或者不能实现
- Shannon理论是现代分组密码算法的基础

# SPN的基本操作

## Substitution

**S-box**

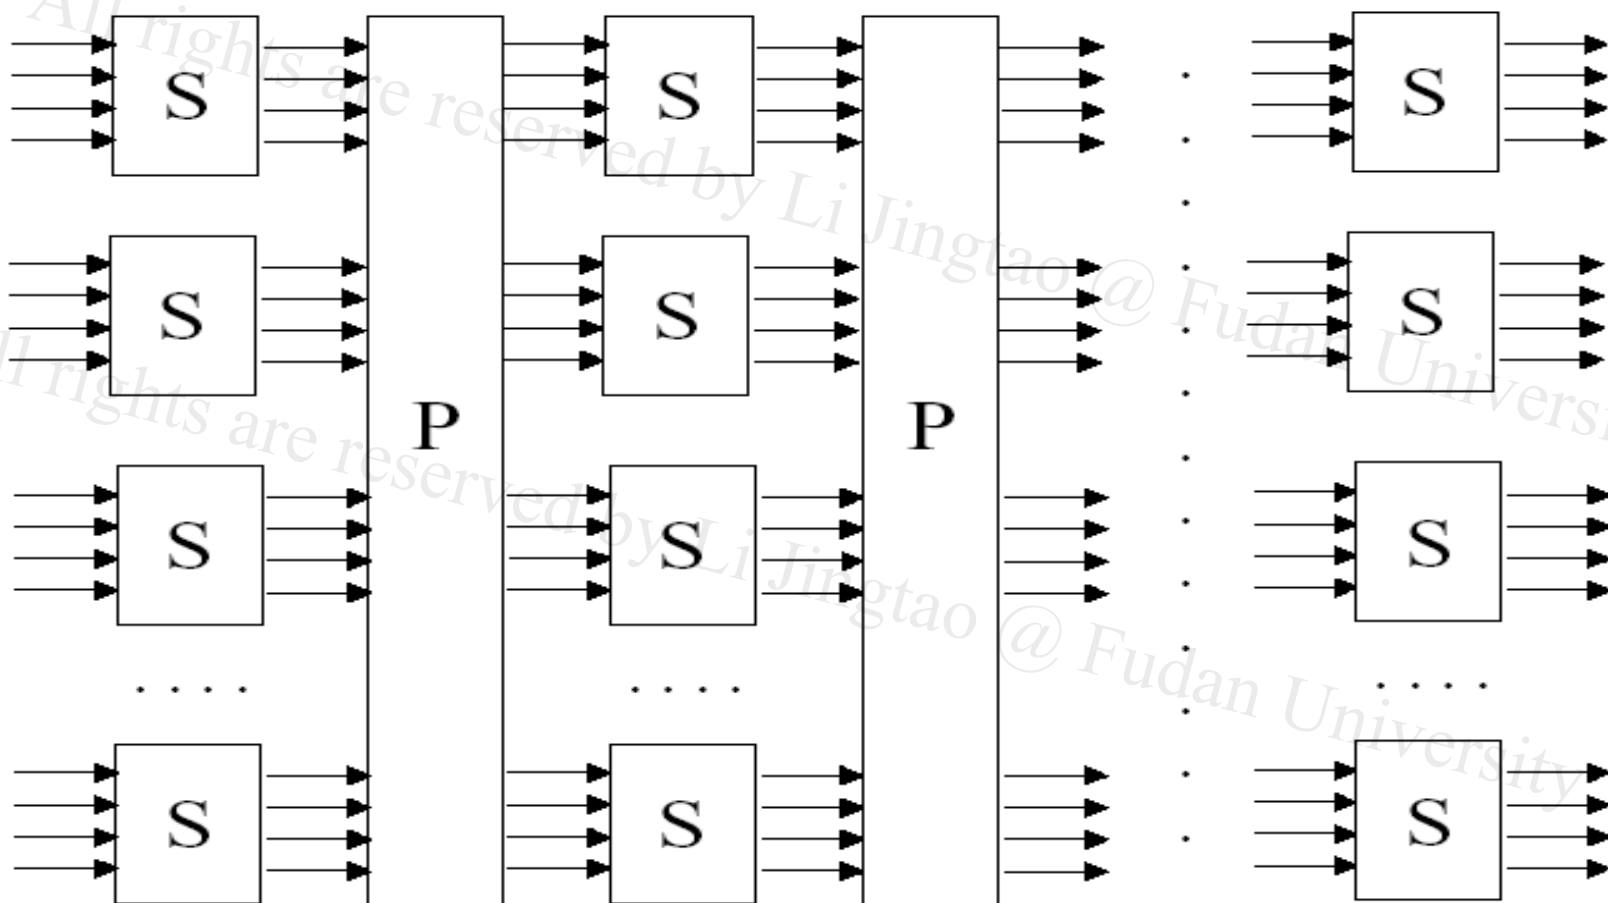

## Permutation

**P-box**

# 16位网络SPN

# SPN的雪崩效应

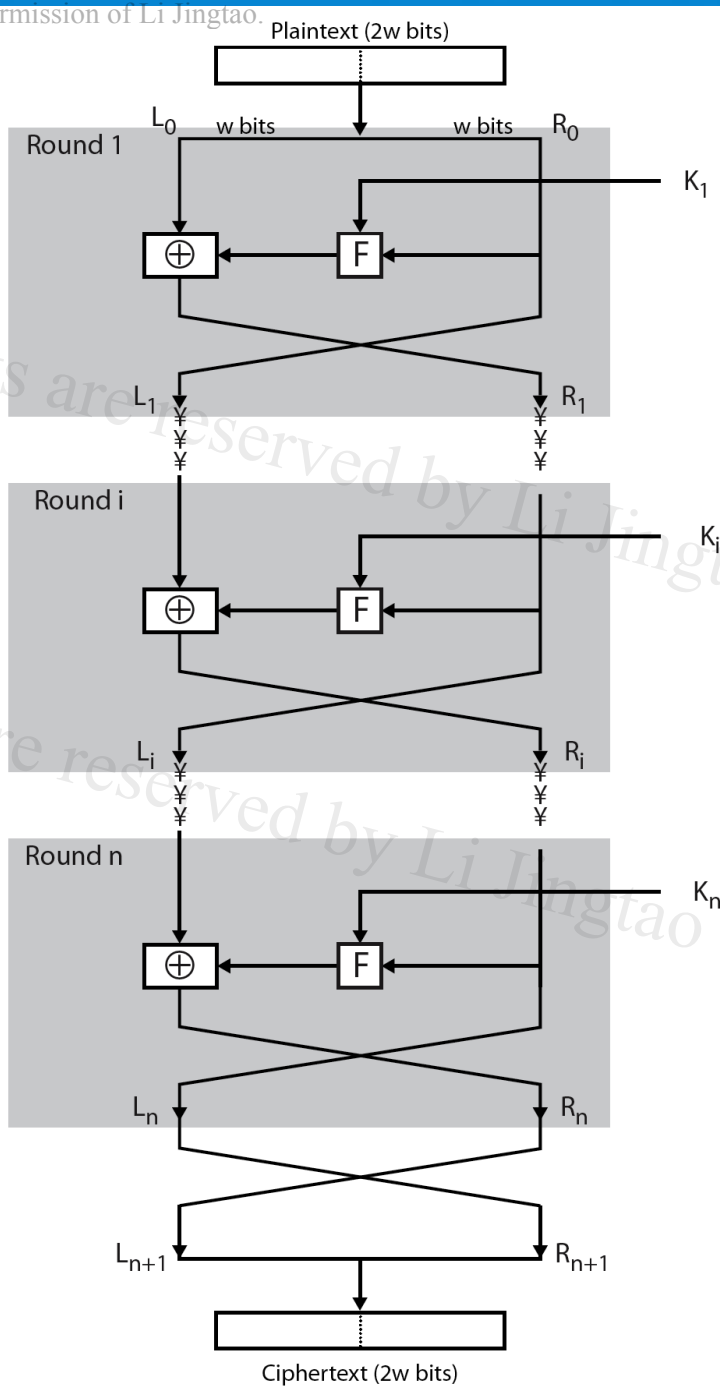

# Feistel Cipher Structure

- Horst Feistel devised the **feistel cipher**
  - based on concept of **invertible** product cipher
- partitions input block into two halves
  - process through multiple rounds which
    - perform a substitution on left data half
    - based on round function of right half & subkey
    - then have permutation swapping halves
- implements Shannon's SPN concept

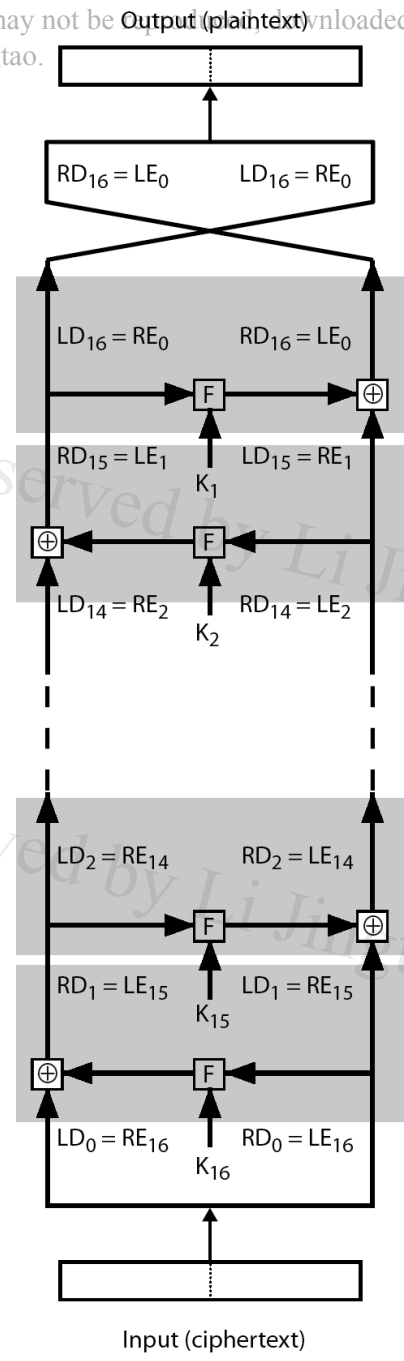

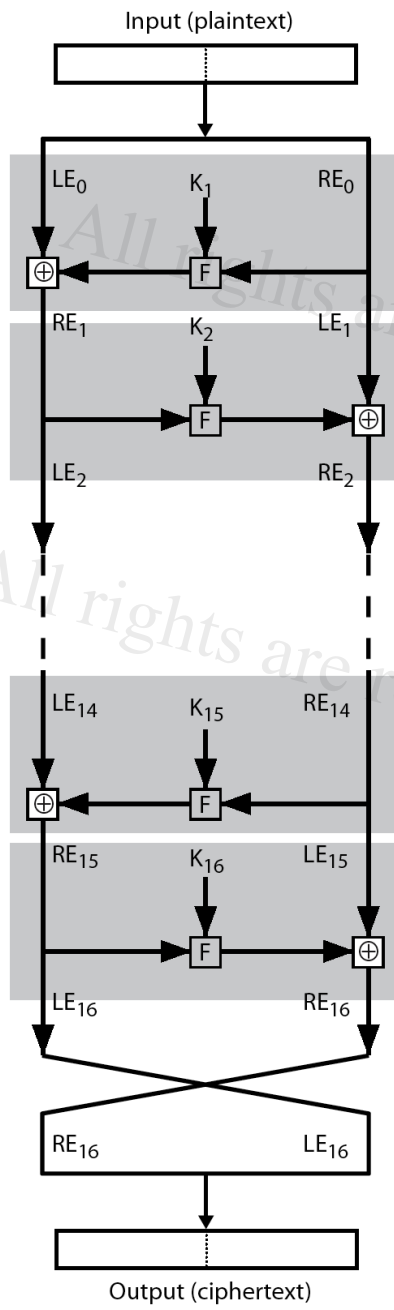

# Feistel Cipher Structure

# Feistel Cipher Design Elements

- block size
- key size
- number of rounds
- subkey generation algorithm
- round function
- Other consideration
  - fast software en/decryption
  - ease of analysis

# Feistel Cipher Decryption

# Data Encryption Standard (DES)

- most widely used block cipher in world
- adopted in 1977 by NBS (now NIST)
  - as FIPS PUB 46
- encrypts 64-bit data using 56-bit key
- has widespread use
- has been considerable controversy over its security
  - NBS (National Bureau of Standards)
  - NIST (National Institute of Standards and Technology)

# DES History

- IBM developed Lucifer cipher
  - by team led by Horst Feistel in late 60's
  - used 64-bit data blocks with 128-bit key
- then redeveloped as a commercial cipher with input from **NSA** and others
- in 1973 NBS issued request for proposals for a national cipher standard
- IBM submitted their revised Lucifer which was eventually accepted as the DES, 1977

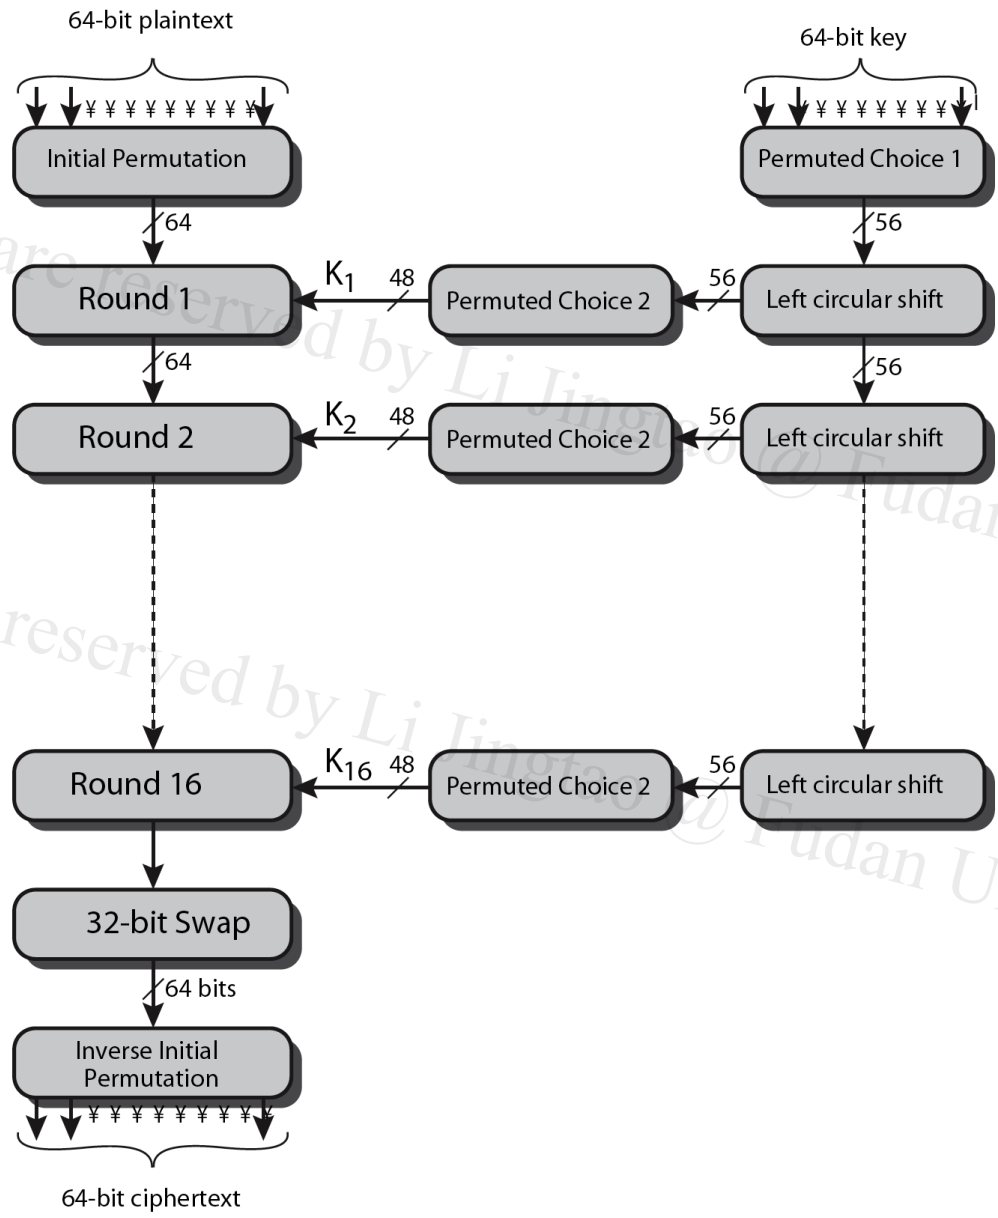

# DES Design Controversy

- although DES standard is public
- was considerable controversy over design
  - in choice of 56-bit key (vs Lucifer 128-bit)
  - and because design criteria were classified
- subsequent events and public analysis show in fact design was appropriate
- use of DES has flourished
  - especially in financial applications
  - still standardised for legacy application use

# DES Encryption Overview

# Initial Permutation, IP

- first step of the data computation
- IP reorders the input data bits
- even bits to LH half, odd bits to RH half
- quite regular in structure (easy in h/w)
- example:

$IP(675a6967 \ 5e5a6b5a) = (ffb2194d \ 004df6fb)$

# DES Round Structure

- uses two 32-bit L & R halves
- as for any Feistel cipher can describe as:

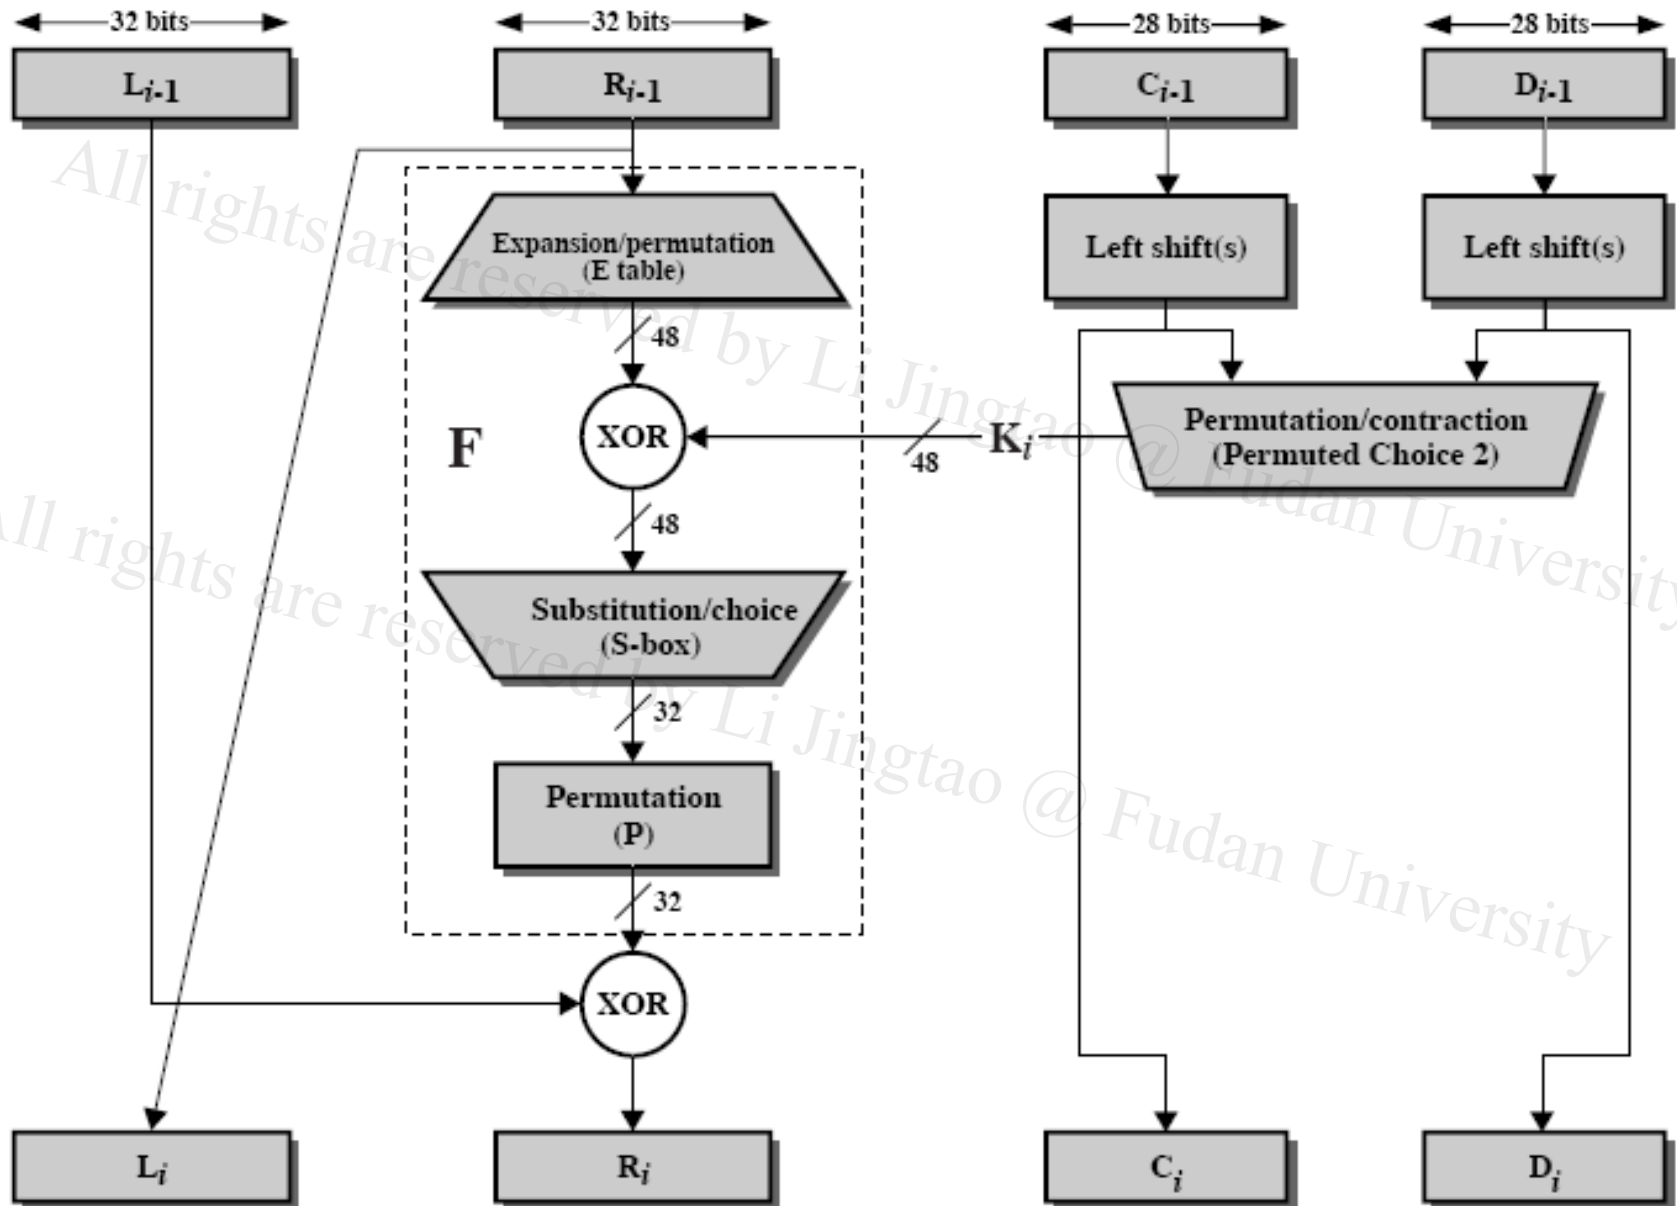

$$L_i = R_{i-1}$$

$$R_i = L_{i-1} \oplus F(R_{i-1}, K_i)$$

- F takes 32-bit R half and 48-bit subkey:
  - expands R to 48-bits using **perm E**
  - adds to subkey using XOR
  - passes through 8 S-boxes to get 32-bit result
  - finally permutes using 32-bit **perm P**

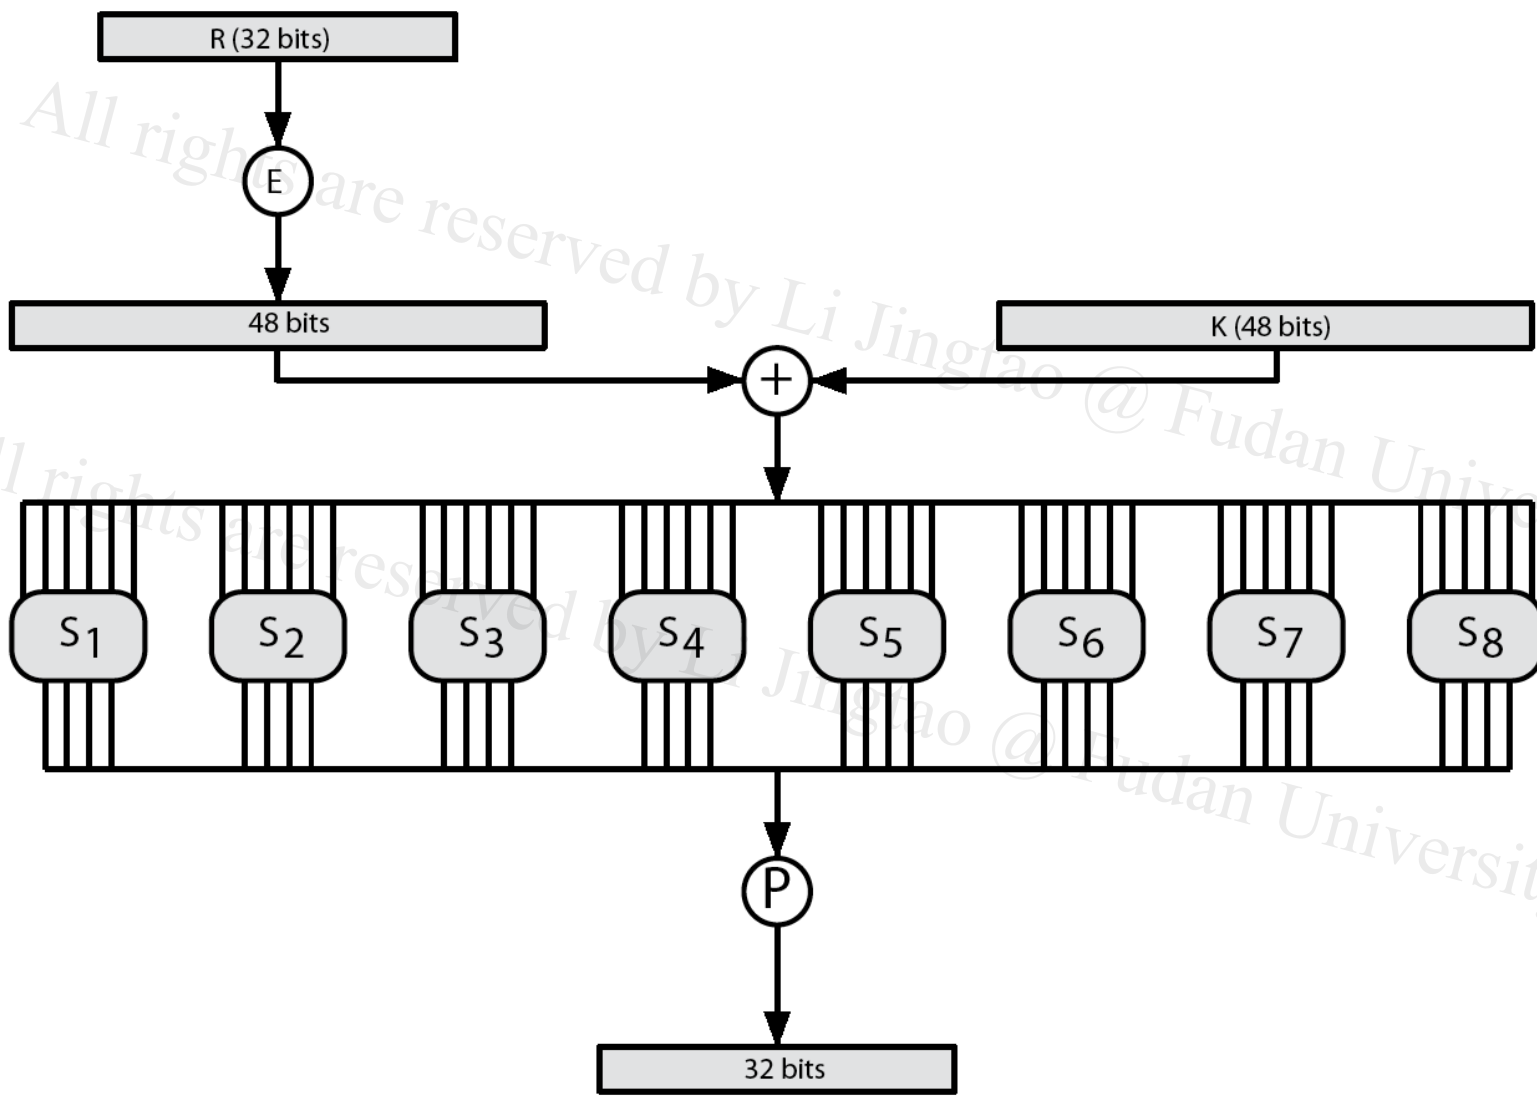

# DES Round Structure

# DES Round Structure

# Substitution Boxes S

- have eight S-boxes which map 6 to 4 bits
- each S-box is actually 4 little 4 bit boxes
  - outer bits 1 & 6 (**row** bits) select one row of 4
  - inner bits 2-5 (**col** bits) are substituted
  - result is 8 lots of 4 bits, or 32 bits
- row selection depends on both data & key
  - feature known as autoclaving (autokeying)
- example:
  - $S(18\ 09\ 12\ 3d\ 11\ 17\ 38\ 39) = 5fd25e03$

# DES Key Schedule

- forms subkeys used in each round
  - initial permutation of the key (PC1) which selects 56-bits in two 28-bit halves
  - 16 stages consisting of:
    - rotating **each half** separately either 1 or 2 places depending on the **key rotation schedule K**
    - selecting 24-bits from each half & permuting them by PC2 for use in round function F
- note practical use issues in h/w vs s/w

# DES Decryption

- decrypt must unwind steps of data computation
- with Feistel design, do encryption steps again using subkeys in reverse order (SK16 ... SK1)
  - IP undoes final FP step of encryption
  - 1st round with SK16 undoes 16th encrypt round
  - ....
  - 16th round with SK1 undoes 1st encrypt round
  - then final FP undoes initial encryption IP
  - thus recovering original data value

# Avalanche Effect

- key desirable property of encryption algorithm
- where a change of **one** input or key bit results in changing approx **half** output bits
- making attempts to analysis by guessing keys impossible
- DES exhibits strong avalanche

# Avalanche Effect

(a) Change in Plaintext		(b) Change in Key	
Round	Number of bits that differ	Round	Number of bits that differ
0	1	0	0
1	6	1	2
2	21	2	14
3	35	3	28
4	39	4	32
5	34	5	30
6	32	6	32
7	31	7	35
8	29	8	34
9	42	9	40
10	44	10	38
11	32	11	31
12	30	12	33
13	30	13	28
14	26	14	26
15	29	15	34
16	34	16	35

# Strength of DES – Key Size

- 56-bit keys have  $2^{56} = 7.2 \times 10^{16}$  values
- brute force search looks hard
- recent advances have shown is possible
  - in 1997 on Internet in a few months
  - in 1998 on dedicated h/w (EFF) in a few days
  - in 1999 above combined in 22hrs!
- still must be able to recognize plaintext
- must now consider alternatives to DES

# DES Design Criteria

- as reported by Coppersmith in [COPP94]
- 7 criteria for S-boxes provide for
  - non-linearity
  - resistance to differential cryptanalysis
  - good confusion
- 3 criteria for permutation P provide for
  - increased diffusion

# Block Cipher Design

- basic principles still like Feistel's in 1970's
- number of rounds
  - more is better, exhaustive search best attack
- function  $f$ :
  - provides “confusion”, is nonlinear, avalanche
  - have issues of how S-boxes are selected
- key schedule
  - complex subkey creation, key avalanche

# AES

- clear a replacement for DES was needed
  - have theoretical attacks that can break it
  - have demonstrated exhaustive key search attacks
- can use Triple-DES – but slow, has small blocks
- US NIST issued call for ciphers in 1997
- 15 candidates accepted in Jun 98
- 5 were shortlisted in Aug-99
- Rijndael was selected as the AES in Oct-2000
- issued as FIPS PUB 197 standard in Nov-2001

# AES Requirements

- symmetric block cipher
- 128-bit data, 128/192/256-bit keys
- stronger & faster than Triple-DES
- active life of 20-30 years (+ archival use)
- provide full specification & design details
- both C & Java implementations
- NIST have released all submissions & unclassified analyses

# Summary

- have considered:
  - block vs stream ciphers
  - Feistel cipher design & structure
  - DES
    - details
    - strength
  - block cipher design principles
